Experiment 6: File Transfer Between Virtual Machines

Aim: To transfer a file from one virtual machine to another using GitHub Codespaces.

Step-by-step procedure

1. Create a GitHub repository

Create a repository named **internal** and add a **README.md** file.

2. Create VM1

Open the repository and choose **Code** → **Codespaces** → **Create codespace on main**.

3. Create a text file in VM1

Open **Terminal** → **New Terminal** and run:

```
echo "This is a text file from Codespace1 to Codespace2" > ~/testfile.txt
```

4. Verify the file in VM1

Run the command below to display the file contents:

```
cat ~/testfile.txt
```

5. Download the file

Copy the file into `/workspaces/internal/`, then download it to your computer using the Explorer.

6. Create VM2

Create a second Codespace from the same repository.

7. Transfer the file to VM2

Upload the downloaded file into the second Codespace using the Explorer. In this session, the copied file appeared as `testfile - Copy.txt`.

8. Verify the file in VM2

Open the terminal in VM2 and run the command below. Use the exact filename if yours differs:

```
cat "testfile - Copy.txt"
```

9. Check the output

Confirm that the displayed text matches the original file.

Expected output

```
This is a text file from Codespace1 to Codespace2
```

Result: The text file was transferred from the first GitHub Codespace to the second and its contents were verified successfully.

Note: This PDF documents the browser-based transfer method used in this session. The original lab document specifies GitHub CLI commands (gh codespace cp), which is a different transfer method.
